

The Babylonian method for computing square roots

Eric Martin, CSE, UNSW

COMP9021 Principles of Programming, trimester 1, 2019

Let a and x be strictly positive real numbers. Let $(x_n)_{n \in \mathbb{N}}$ be the sequence defined as:

- $x_0 = x$;
- for all $n \in \mathbb{N}$, $x_{n+1} = \frac{1}{2}(x_n + \frac{a}{x_n})$.

If $x_n = \sqrt{a}$ for some $n \in \mathbb{N}$, then clearly $x_m = \sqrt{a}$ for all $m \geq n$. Note that given $n \in \mathbb{N}$, if $x_n < \sqrt{a}$ then $\frac{a}{x_n} > \sqrt{a}$, and if $x_n > \sqrt{a}$ then $\frac{a}{x_n} < \sqrt{a}$, so x_{n+1} is the average of a number that is smaller with \sqrt{a} with a number that is greater than \sqrt{a} . Actually, $(x_n)_{n \in \mathbb{N}}$ quadratically converges to \sqrt{a} , as we now show. For all $n \in \mathbb{N}$, set $\varepsilon_n = \frac{x_n}{\sqrt{a}} - 1$. It suffices to show that:

1. $(\varepsilon_n)_{n \in \mathbb{N}}$ converges to 0, and
2. when n is large enough, $\varepsilon_{n+1} < \varepsilon_n^2$.

It is trivially verified by induction that $x_n > 0$ for all $n \in \mathbb{N}$, hence $\varepsilon_n > -1$ for all $n \in \mathbb{N}$. Let $n \in \mathbb{N}$ be given. Then $\varepsilon_{n+1} = \frac{x_{n+1}}{\sqrt{a}} - 1 = \frac{x_n + \frac{a}{x_n}}{2\sqrt{a}} - 1 = \frac{x_n^2 + a - 2\sqrt{a}x_n}{2\sqrt{a}x_n}$. Also, $\varepsilon_n^2 = (\frac{x_n - \sqrt{a}}{\sqrt{a}})^2 = \frac{x_n^2 - 2x_n\sqrt{a} + a}{a}$ and $\sqrt{a} = \frac{x_n}{1 + \varepsilon_n}$. Hence $\varepsilon_{n+1} = \frac{\varepsilon_n^2 \sqrt{a}}{2x_n} = \frac{\varepsilon_n^2}{2(1 + \varepsilon_n)}$; in particular, $\varepsilon_{n+1} \geq 0$. It follows that for all $n > 0$:

- $\varepsilon_{n+1} \leq \frac{\varepsilon_n^2}{2(1+0)} = \frac{\varepsilon_n^2}{2}$
- $\varepsilon_{n+1} \leq \frac{\varepsilon_n^2}{2(\varepsilon_n)} = \frac{\varepsilon_n}{2}$

that is, $\varepsilon_{n+1} \leq \min(\frac{\varepsilon_n^2}{2}, \frac{\varepsilon_n}{2})$, from which 1 and 2 follow immediately.

The following generator function allows one to generate on demand an initial segment of a sequence of the form $(f(x), f^2(x), f^3(x), f^4(x), \dots)$:

```
In [1]: def iterate(f, x):  
        while True:  
            next_x = f(x)  
            yield next_x  
            x = next_x
```

Applied to $f : x \mapsto x + 3$ and $x = 5$, `iterate()` is a generator for the sequence $(5 + 3, (5 + 3) + 3, ((5 + 3) + 3) + 3, (((5 + 3) + 3) + 3) + 3, \dots)$:

```
In [2]: S = iterate(lambda x: x + 3, 5)  
        next(S)  
        next(S)  
        next(S)  
        next(S)
```

Out[2]: 17

Let x_0 be a strictly positive integer. For all $n \in \mathbb{N}$, let x_{n+1} be $\frac{n}{2}$ if n is even, and $3x + 1$ otherwise. The Collatz conjecture states that 1 eventually occurs in $(x_n)_{n \in \mathbb{N}}$; equivalently, $(x_n)_{n \in \mathbb{N}}$ ends in $(1, 4, 2, 1, 4, 2, \dots)$. If we want to use `iterate()` and get a generator for such a sequence, we can pass as a first argument to `iterate()` a lambda expression, even though lambda expressions cannot contain `if` statements; indeed, we can take advantage of the way Boolean expressions are evaluated, as illustrated below:

```
In [3]: # None, 0, '', {}, [], () all evaluate to False
        # 2, [3], 4.5 all evaluate to True
        # Only when () is processed can we conclude
        # that the expression is false
        None or 0 or '' or {} or [] or ()
        # When 2 is processed, and not before, we can conclude
        # that the expression is true
        None or 0 or '' or {} or [] or () or 2 or [3] or 4.5
        # Only when 4.5 is processed can we conclude
        # that the expression is true
        2 and [3] and 4.5
        # When {} is processed, and not before, we can conclude
        # that the expression is false
        2 and [3] and 4.5 and {} and [] and () and '' and 0 and None
```

Out[3]: ()

Out[3]: 2

Out[3]: 4.5

Out[3]: {}

So we can define the sequence of interest with the lambda expression `lambda x: x % 2 == 0 and x // 2 or 3 * x`; we pass it as first argument to `iterate()` to generate the first few members of that sequence for $x_0 = 2$, $x_0 = 3$, $x_0 = 6$, and $x_0 = 7$:

```
In [4]: S = lambda a: iterate(lambda x: x % 2 == 0 and x // 2 or 3 * x + 1, a)
```

```
S_2 = S(2)
[next(S_2) for _ in range(10)]
```

```
S_3 = S(3)
[next(S_3) for _ in range(10)]
```

```
S_6 = S(6)
[next(S_6) for _ in range(10)]
```

```
S_7 = S(7)
[next(S_7) for _ in range(20)]
```

```
Out[4]: [1, 4, 2, 1, 4, 2, 1, 4, 2, 1]
```

```
Out[4]: [10, 5, 16, 8, 4, 2, 1, 4, 2, 1]
```

```
Out[4]: [3, 10, 5, 16, 8, 4, 2, 1, 4, 2]
```

```
Out[4]: [22, 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1, 4, 2, 1, 4]
```

Let us use `iterate()` to compute approximations of the square roots of 2 and 3, starting with initial guesses of 100 and 1,000, respectively:

```
In [5]: S = lambda x: lambda a: iterate(lambda x: (x + a / x) / 2 , x)
```

```
S_100_2 = S(100)(2)
list(next(S_100_2) for _ in range(12))
```

```
S_1000_3 = S(1_000)(3)
list(next(S_1000_3) for _ in range(15))
```

```

We make `iterate()` an **inner function** of a function `square_root()` meant to compute the square root of its first argument, up to a precision given by its second argument:

```
In [6]: def square_root(a, ε):  
        def iterate(f, x):  
            while True:  
                next_x = f(x)  
                yield next_x  
                x = next_x  
  
        x = 1  
        approximating_sequence = iterate(lambda x: (x + a / x) / 2 , x)  
        next_x = next(approximating_sequence)  
        while abs(next_x - x) > ε:  
            next_x, x = next(approximating_sequence), next_x  
        return next_x
```

```
In [7]: square_root(2, 0.000001)  
        square_root(3, 0.000001)
```

```
Out[7]: 1.414213562373095
```

```
